

Tranformations of consciousness.

Mauro Nelson Maldonato¹

Quantitative-categorial and qualitative-dimensional analyses of consciousness show how this latter is a well-organized albeit limited whole of meanings and dimensions, as well as a temporary, transitory and synchronic structure. A number of evidence show that there is a spontaneous transformative ability of the consciousness, across its different stages with no conditioning by the environment. The electrophysiological analysis and the Brain CT-scan techniques show different stages of the consciousness, its transition either from alertness to sleep or from excited hyper-alertness to the absence of consciousness (disease). The aim of this work is to clarify: how awareness organizes itself through the structure of the consciousness field; how syntony between consciousness and related neurophysiological processes as well as individual and alterego polarity lay at the bases of somatic life, and namely in its adaptability to each environmental situation.
